

The artifact that I have enhanced is the dashboard to a pyMongo database for animal shelters geared towards search and rescue. The dashboard includes a listing of the various animals available, their breed, and what kind of rescue they work for. One of the options on the dashboard already existing was the ability to toggle the list by types of rescues such as “water rescue” or “mountain rescue.” To enhance this, I added more options for searching the list and seeing only what you want to see. One was to add toggling dogs and cats so the user can see just cats or just dogs. Another one was adding a dropdown box to allow different breeds of dogs to be selected.

This artifact is important due to its backend and frontend work for software development, making both the database and a dashboard to interact with. It shows a skill in multiple different programming languages and the ability to integrate the languages into one project. This shows the ability to design and evaluate computing solutions along with the ability to use innovative techniques and skills. Most software design and engineering requires the ability to work in multiple languages.

My specific interest is in working with databases and data analysis. This enhancement shows the ability to create a database with Create, Read, Update, and Delete methods that work through a front-end dashboard. I learned how to integrate and update already existing projects by working on them in pieces and checking throughout the enhancement process. Ensuring that additions to a project don't break the original project is vital work.
